1. General aspects and materials

Materials and reagents were of the highest commercially available grade and used without further purification. Reactions were monitored by thin layer chromatography using Merck silica gel 60 F_{254} plates. Compounds were visualized by UV and KMnO₄. Flash chromatography was performed using Merck silica gel 60, particle size 40 - 63 μm. ¹H and ¹³C NMR spectra were recorded on a Bruker DPX 400 spectrometer. Chemical shifts are reported in ppm using TMS or the residual solvent peak as a reference. HPLC analyses were performed on an analytical HPLC with a diode array detector from Shimadzu. Specific rotations were measured on a Perkin Elmer Polarimeter 341. For automated peptide synthesis, a Syro I Peptide Synthesizer (MultiSynTech GmbH, Witten, Germany) was employed.

2. Synthesis of peptidic catalysts

a. General protocols for solid phase synthesis

Peptides were prepared on solid phase (Rink Amide resin) following the general protocol for Fmoc/Bu peptide synthesis.

*General procedure for peptide couplings:* ¹PrNE₂ (9 eq as a 3M solution in N-methylpyrrolidone) was added to a solution of Fmoc-Xxx-OH (3 eq) and HCTU (3 eq) in DMF. The activated amino acid was added to the amino-functionalized resin, swollen in DMF (≈100 mM concentration) and the mixture was agitated for 1.5 h before washing with DMF (5x).

*General procedure for Fmoc-deprotections:* 40% piperidine in DMF was added to the resin (preswollen in DMF) and the reaction mixture was agitated for 3 min, drained and the piperidine treatment repeated for 10 min. Finally the resin was washed with DMF (7x).

*General procedure for cleavage of peptides from the solid support:* The solid supported peptides were cleaved from the Rink Amide resin by stirring in a mixture of TFA:CH₂Cl₂ 2:1 for 1 h and a second time for 20 min. Pooling of filtrates and removal of all volatiles under reduced pressure followed by precipitation with Et₂O afforded the peptides 1-4.

3. General procedure of 1,4-addition reactions of aldehydes to nitroolefins

*N*-methylmorpholine (5.0 μl, 0.045 mmol, 0.1 eq) was dissolved in the specified solvent (10 ml). 1 ml of this solution was added to the catalyst (2.0 mg, 4.54 μmol, 0.01 eq) and the mixture was stirred for 5 min. The nitroolefin (1 eq) and the aldehyde (3 eq) were added and the reaction mixture was stirred at the specified temperature. The progress of the reaction was followed by TLC. After completion, the reaction mixture was directly separated by flash column chromatography on silica gel eluting with a mixture of pentanes and ethyl acetate.

4. Characterisation of 1,4-addition products

Assignment of the stereoisomers was performed by comparison with literature and chromatographic data obtained using diastereomeric peptides 1 and 4 as catalysts for reactions performed under otherwise identical conditions. Peptides 1 and 4 have opposite enantioselectivity.

5. Conformational analysis of peptides 2-4 using MacroModel 8.0:

The calculations used the OPLS-AA force field[7] and the GB/SA model for chloroform.[8] Searching was performed using the MCMM method in blocks of 20000 steps.

Lowest energy structures of peptides 1-4:
Overlay of the lowest energy structures of peptides H-Pro-Pro-Asp-NH₂ 1 and H-D-Pro-Pro-Asp-NH₂ 4:

Peptide 1 in grey and peptide 4 in green illustrating that the two conformations are identical apart from the N-terminal proline (Pro) residues which point into opposite directions.

6. Catalytic Properties of Peptides with Protecting Groups on the Secondary Amine or Carboxylic Acid

To analyze the importance of the secondary amine and the carboxylic acid within the catalyst structure, the catalytic properties of Ac-D-Pro-Pro-Asp-NH₂ 5 and H-D-Pro-Pro-Asp(OtBu)-NH₂ 5 were examined as catalysts for the reaction between butanal and nitrostyrene. No product formation was observed when as much as 10 mol% of peptide 5 was employed, suggesting that enamine formation is crucial for catalysis. Peptide 6 is still catalytically active but has lower activity and selectivity (1 mol% of 6 provided the product in a yield of 20% within 24 hours with a selectivity of 73% ee). Similar results were obtained when the dipeptide H-Pro-Pro-OH was employed as a catalyst (52% yield, 68% ee).
