General Directions

Chromatography: Flash chromatography was performed on silica gel (Merck Kieselgel 60, 230-400 mesh) unless otherwise stated. TLC was performed on aluminium-backed silica plates (60F254, 0.2 mm). Optical rotations were measured using a Perkin-Elmer 241 MC polarimeter. [α]D values are given in angular degrees per g/cm³. Infrared spectra were recorded on a Perkin-Elmer Spectrum One FT-IR spectrometer. Chemical shifts (δH) are quoted in parts per million (ppm), J values are given in Hz. Chemical shifts (δC) are quoted in parts per million (ppm), referenced to the appropriate residual solvent peak and are assigned as s, d, t, q for C, CH, CH₂, CH₃. COSY, HMBC and HMQC were used where necessary in assigning NMR spectra. Anhydrous THF, CH₂Cl₂, Et₂O and toluene were obtained from a purification column composed of activated alumina (A-2). Other anhydrous solvents were used as obtained from Aldrich.

2-Bromoethyl trifluoromethanesulfonate

![2-Bromoethyl trifluoromethanesulfonate](image)

Trifluoromethanesulfonic anhydride (10.0 g, 35.4 mmol) was added drop-wise to a stirred solution of pyridine (2.98 mL, 36.8 mmol) in anhydrous CH₂Cl₂ (35 mL) at –20 °C under nitrogen and allowed to stir for 10 minutes. 2-Bromoethanol (4.25 g, 34.0 mmol) was added drop-wise to the reaction mixture. The cooling bath was removed and the reaction stirred for a further 10 minutes (do not allow more than this time) while warming. The resulting suspension was filtered, concentrated (using a rotary evaporator, keeping the water bath temp below 20 °C) and petroleum ether (30 mL) was added. The mixture was filtered and concentrated again under reduced pressure and finally dried under high vacuum to give the title product as a clear colorless oil (7.17 g, 82%). It was used immediately in the next step without further purification. δH (400 MHz; CDCl₃) 4.70 (2 H, t, J 6.5, TfO-CH₂), 3.55 (2 H, t, J 6.5, Br-CH₂) δC (100 MHz; CDCl₃) 74.5 (t), 26.1 (t).
A solution of 2-bromoethyl trifluoromethanesulfonate \(2\) (3.24 g, 12.6 mmol) in anhydrous toluene (10 mL) was treated with phenyl sulfide (2.81 g, 15.1 mmol) at RT under nitrogen with stirring. The reaction mixture was then heated at 100 °C under nitrogen for 5 h. The solution was allowed to cool to RT and diethyl ether (20 mL) was added to precipitate the product \(7\) which was isolated by filtration as a white powder (4.51 g, 81%) after washing with Et\(_2\)O and used in the next step without further purification.\(^3\) mp 85–87 °C (precipitated from toluene/Et\(_2\)O) [lit.\(^2\) 86.5–88 °C (precipitated from Et\(_2\)O/CH\(_2\)Cl\(_2\))] \(R_f\) (MeOH-CH\(_2\)Cl\(_2\), 1:9) 0.20; \(\delta_H\) (400 MHz; CDCl\(_3\)) 8.13-8.06 (4 H, m, ArH), 7.78-7.67 (6 H, m, ArH), 4.86 (2 H, t, \(J\) 6.5, S+-CH\(_2\)), 3.67 (2 H, t, \(J\) 6.5, Br-CH\(_2\)); \(\delta_c\) (100.5 MHz; CDCl\(_3\)) 135.3 (s), 131.9 (d), 131.2 (d), 122.9 (d), 48.3 (t), 23.8 (t).

The above reaction can also be performed using trifluorotoluene instead of toluene. On cooling white crystals form. Et\(_2\)O was added to assist mobilization. Filtration and washing with Et\(_2\)O afforded \(7\) as white crystals (80% yield). mp 84–87 °C (trifluorotoluene). NMR spectra were identical to when toluene was used.

**Diphenylvinylsulfonium trifluoromethanesulfonate \(1\)**

(2-Bromoethyl)diphenylsulfonium trifluoromethanesulfonate \(7\) (5.69 g, 12.8 mmol) was dissolved into THF / H\(_2\)O (2:1) (21 mL). KHCO\(_3\) (1.54 g, 15.4 mmol) was added and the reaction mixture was stirred for 20 min at RT (do not allow more than this time). The solvent was evaporated immediately under reduced pressure (using a rotary evaporator connected to a high vacuum pump and keeping the water bath temperature below 20 °C) and then redissolved in CH\(_2\)Cl\(_2\) (40 mL), dried over MgSO\(_4\), filtered and evaporated. The residue was redissolved in CH\(_2\)Cl\(_2\) (10 mL), loaded on a silica bed (4 cm depth and 2.5 cm diameter), the resulting band was covered with 1 cm sand, eluted
with CH$_2$Cl$_2$ (400 mL), followed by 10% MeOH in CH$_2$Cl$_2$ (200 mL) the product 1 was isolated as a light yellow oil (4.45 g, 96%). $R_f$ 0.31 (20% MeOH in CH$_2$Cl$_2$); $\delta_H$ (400 MHz; CDCl$_3$) 7.93-7.82 (4 H, m, ArH), 7.75-7.64 (6 H, m, ArH), 7.51 (1 H, dd, $J$ 16.5, 9.5, CH$_2$=CH), 6.72 (1 H, dd, $J$ 9.5, 2.5, HHC=CH), 6.57 (1 H, dd, $J$ 16.5, 2.5, HHC=CH); $\delta_C$ (100.5 MHz; CDCl$_3$) 138.1 (t), 134.6 (d), 131.6 (d), 130.5 (d), 125.0 (s), 123.4 (d).

Compound 1 is stable at RT for at least 6 months (we have never observed decomposition during storage), but it is slightly hydroscopic and should be stored appropriately (under nitrogen/argon in a container sealed with parafilm). Sometimes a dark green/black colored product 1 was obtained (this was observed if a bottle of old triflic anhydride was used in the synthesis of 2-bromoethyl trifluoromethanesulfonate) but it could be used in the chemistry described below without detriment.

Diisopropyl(vinyl)sulfonium trifluoromethanesulfonate was synthesized according to a literature procedure.²
A solution of 2-bromoethyl trifluoromethanesulfonate\(^2\) (3.40 g, 13.2 mmol) in CH\(_2\)Cl\(_2\) (25 mL) was treated with tetrahydrothiophene (1.20 g, 13.6 mmol) drop-wise over 5 min at RT under nitrogen with stirring. The reaction mixture was then refluxed under nitrogen at 45 °C for 1 d. The CH\(_2\)Cl\(_2\) was removed under vacuum and anhydrous diethyl ether (20 mL) was added to the resulting residue and it was stirred for 1 h to precipitate the product 1-(2-bromoethyl)tetrahydro-1H-thiophenium trifluoromethanesulfonate \(12\), which was isolated by filtration as a white solid (3.00 g, 66%) and was used in the next step without further purification.

A suspension of \(12\) (4.70 g, 13.6 mmol) and silver (I) oxide (6.30 g, 27.2 mmol) in deionized water (10 mL) and THF (10 mL) was stirred for 20 h at RT. Then the reaction mixture was filtered through Celite and the filtrate was concentrated under reduced pressure. The residue was dissolved in CH\(_2\)Cl\(_2\) (30 mL), dried over MgSO\(_4\), filtered, evaporated and the residue was again dissolved in CH\(_2\)Cl\(_2\) (10 mL) and passed through silica. The residue was washed with CH\(_2\)Cl\(_2\) (200 mL) and then with 10% MeOH in CH\(_2\)Cl\(_2\). The solvent was removed under vacuum and the desired product \(11\) was isolated as a clear oil (2.00 g, 56%); \(R_t\) 0.16 (MeOH-DCM, 1:10); \(\delta_H\) (400 MHz; CDCl\(_3\)) 6.73 (1 H, dd, \(J_{16.5, 9.0}, CH_2=CH\)), 6.44 (1 H, dd, \(J_{16.5, 2.5}, HHC=CH\)), 6.35 (1 H, dd, \(J_{9.0, 2.5}, HHC=CH\)), 3.94 (2 H, m, SCH\(_2\)), 3.54 (2 H, m, SCH\(_2\)), 2.46 (4 H, m, SCH\(_2\)CH\(_2\)CH\(_2\)); \(\delta_C\) (100 MHz; CDCl\(_3\)) 135.3 (d), 124.3 (t), 47.2 (t), 28.9 (t); \(v_{max}(neat)/cm^{-1}\) 1450, 1426, 1256, 1165, 1030; \(m/z\) (CI\(^+\)) 115 (M–OTf); HRMS (CI\(^+\)) C\(_6\)H\(_{11}\)S requires: 115.0581; found 115.0581.
Use of primary amines, carbamates and amides as substrates

Treatment of norephedrine with vinyl sulfonium salt in the presence of DBU afforded aziridine 13 (Scheme 1). In 2003 Mukaiyama reported similar chemistry, where aziridines were obtained by treating primary amines with vinyl sulfonium salts. When NaH was used a highly polar product resulted which was difficult to isolate (Scheme 1). Use of carbamate and amide substrates did not lead to any cyclization with a range of bases (Scheme 2).
